Spatial and Temporal Trends of Number of Deaths Attributable to Ambient PM$_{2.5}$ in the Korea

Changwoo Han, Soontae Kim, Youn-Hee Lim, Hyun-Joo Bae, and Yun-Chul Hong

ABSTRACT

**Background:** We aimed to evaluate the spatial and temporal trends of the health burden attributable to particulate matter less than 2.5 µm in diameter (PM$_{2.5}$) in the metropolitan cities and provinces of the Korea.

**Methods:** We used modeled PM$_{2.5}$ concentration data for the basic administrative levels, comprising the cities and the provinces of Korea, the corresponding annual population census data for each level, and the age and cause specific mortality data. We applied cause-specific integrated exposure-response functions to calculate the premature mortality attributable to ambient PM$_{2.5}$ for four disease endpoints (ischemic heart disease [IHD], chronic obstructive pulmonary disease [COPD], lung cancer [LC], and cerebrovascular disease [stroke]) for the year 2015. Moreover, the temporal trends of the health burden from 2006 to 2015 were assessed.

**Results:** The annual average PM$_{2.5}$ concentration for Korea was 24.4 µg/m$^3$, and 11,924 premature deaths were attributable to PM$_{2.5}$ exposure in 2015. By simulating the reduction in the annual mean values of PM$_{2.5}$ to 10 µg/m$^3$, about 8,539 premature deaths were preventable. There was spatial variation in mortality burden attributable to PM$_{2.5}$ across the sub-national regions of Korea. In particular, the high burden was concentrated at Seoul and Gyeonggi province due to the high population density. However, decreasing trends were noted for most of the metropolitan cities and provinces of Korea since 2006.

**Conclusion:** Our findings show that further actions to improve air quality in Korea would substantially improve the health burden due to particulate matter.

**Keywords:** Particulate Matter; Health Burden; Mortality; Korea

INTRODUCTION

Particulate matter 2.5 µm or less in diameter (PM$_{2.5}$) is becoming a global health threat. Previous systematic reviews of epidemiologic studies revealed causal relationships between PM$_{2.5}$ exposure and mortality outcomes such as ischemic heart disease, chronic obstructive pulmonary disease, lung cancer, and cerebrovascular disease. According to a recent report from the World Health Organization (WHO), a global estimation of about 3 million deaths...
and 84 million disability-adjusted life years (DALYs) were attributable to the ambient PM$_{2.5}$ exposure in 2012. The Global Burden of Disease (GBD) group reported that ambient PM$_{2.5}$ is the fifth ranking mortality risk factor, which accounts for the 4.2 million deaths and 103 million DALYs in 2015. Due to increasing number of studies reporting possible associations between ambient particulate matter exposure and diverse health outcomes, total disease burden from particulate matter exposure might be higher than the current estimation indicate.

There is a growing public interest regarding PM$_{2.5}$ in the Republic of Korea. Among the Organization for Economic Co-operation and Development (OECD) countries, Korea has the second highest population weighted annual PM$_{2.5}$ exposure levels with 29 $\mu$g/m$^3$ in 2015. Decreasing trends of the annual particulate matter concentrations has been flattened in recent years, and days with high concentrations of particulate matter has been increased in Korea. To meet the increasing public demands, the government of Korea commenced a sub-national level forecasting system on particulate matter 10 $\mu$m or less in diameter (PM$_{10}$) and PM$_{2.5}$ from February 2014 and January 2015, respectively. The government unveiled special management measures to deal with PM$_{2.5}$ in June 2016 and, as part of the process, eight old coal-fired power plants (30 years or older) were shut down for 1 month in June 2017.

Recent health impact assessment of air pollution from the global levels of estimation indicates that 11,523 and 18,148 deaths were attributable to ambient PM$_{2.5}$ exposure in Korea for 2012 and 2015, respectively. However, no study has been conducted at the sub-national levels to evaluate the spatial distribution and the temporal trends of the health burden across Korea. Therefore, in this study, we conducted a sub-national level analysis to estimate the health burden attributable to PM$_{2.5}$ exposure and evaluated the temporal trends of the health burden in Korea. We used the latest publicly available population structure and mortality data with modeled PM$_{2.5}$ concentration covering all the sub-national regions of the country from 2006 to 2015.

**METHODS**

**Study design**

Korea is composed of eight metropolitan cities and nine provinces. Each metropolitan city is composed of ‘gu’ while provinces are composed of ‘si’ and ‘gun,’ which are the basic administration units of Korea. To calculate the number of deaths attributable to PM$_{2.5}$ in the sub-national level, we need following three information: 1) annual PM$_{2.5}$ concentrations, 2) the population structure, 3) age and disease specific mortality rates. For this study, annual PM$_{2.5}$ concentration and the population structure data were collected in basic administrative unit levels, while the mortality data were collected in metropolitan cities or the province level.

**PM$_{2.5}$ exposure data**

We used a Weather Research and Forecast (WRF, version 3.3.1) - Sparse Matrix Operator Kernel Emission (SMOKE, version 3.1) - Community Multiscale Air Quality (CMAQ, version 4.7.1) system to prepare daily PM$_{2.5}$ concentration from 2006 to 2015 in the basic administrative unit levels. Details of the modeling methodologies and validation results are presented in a previous research articles. In brief, we utilized the modeling system to
estimate formation, transport, and removal of PM$_{2.5}$. We used the CMAQ with the AERO5 aerosol module and the Statewide Air Pollution Research Center version 99 to simulate air quality in Korea. We conducted meteorology simulation using WRF with the National Center for Environmental Protection FNL (Final) data as the initial field. The CMAQ-ready meteorological inputs were prepared using the Meteorology Chemistry Interface Processor version 3.6. For anthropogenic emissions, the Korean National Emissions Inventory named Clean Air Policy Support System 2010 was processed with SMOKE. Biogenic emissions were estimated with the Model of Emissions of Gases and Aerosols from Nature (MEGAN). We adopted two modeling domains with horizontal resolutions of 27-km and 9-km. The coarse modeling domain covers the Northeast Asia including China, Japan, and Korea. Simulation results from the coarse modeling domain was used to derive the boundary conditions for the 9-km modeling domain. Gridded hourly PM$_{2.5}$ concentrations from CMAQ simulations for the fine model domain were then resampled for each administration in Korea based on a GIS shape file. During the process, hourly PM$_{2.5}$ observation data were nudged on the modeling field to minimize model uncertainties.

**Population structure and the mortality rate data**

To calculate the health burden attributable to PM$_{2.5}$, we used the 2015 population census data, which are the results of the complete enumeration survey. Owing to the enumeration surveys being conducted every five years, we used the mid-year population of the resident registration data from 2006 to 2015 to estimate the temporal trends of the health burden. The number of the population for different age groups (25–29, 30–34, 35–39, 40–44, 45–49, 50–54, 55–59, 60–64, 65–69, 70–74, 75–79, and 80–) in each administrative unit (‘si,’ ‘gun,’ and ‘gu’) were collected from the Korean Statistical Information Service website.\(^{11}\)

Mortality data of each city and province were collected from the Korean Statistical Information Service MicroData Integrated Service homepage.\(^{12}\) We selected the following four disease endpoints (corresponding International Classification of Disease, 10th revision code): ischemic heart disease (IHD, I20–I25), chronic obstructive pulmonary disease (COPD, J40–J44), lung cancer (LC, C33–C34), and cerebrovascular disease (stroke, I60–I69) to calculate the health burden attributable to PM$_{2.5}$ exposure. Disease outcomes were selected based on the epidemiological studies indicating their robust causal relationship with PM$_{2.5}$ exposure.\(^{1,13}\) Age-specific mortality rate (/100,000 persons) was calculated for the city or province levels by dividing the number of yearly age groups, and cause-specific mortality rate with the corresponding mid-year population. We calculated the city or province level mortality rates because public deaths registration data were unavailable in basic administration unit levels.

**Statistical analysis**

We applied cause-specific integrated exposure-response (IER) functions developed for the Global Burden of Disease 2010 and 2013 to estimate the premature mortality attributable to ambient PM$_{2.5}$.\(^{13}\) In previous health impact assessment studies, researchers used diverse concentration-mortality functions based on epidemiological cohort studies to estimate the health burden attributable to PM$_{2.5}$. However, most of the previous studies were conducted in Western regions where PM$_{2.5}$ concentrations were relatively low, resulting in uncertainties regarding concentration-mortality functions at higher PM$_{2.5}$ concentration. Therefore, researchers integrated the relative risk (RR) values of diverse sources of PM$_{2.5}$ such as the second-hand tobacco smoking, active tobacco smoking, and the household air pollution from burning solid fuels to estimate the concentration-mortality functions in higher PM$_{2.5}$ concentrations.
concentration. The IER functions have been widely used by the WHO, GBD groups, and other researchers for estimating the health burden attributable to PM$_{2.5}$.\textsuperscript{2,3,14}

Based on previous research article which provided parameters for the calculated IER functions, we calculated the mean values of RR and their 95% confidence intervals for PM$_{2.5}$ concentrations ranging from 0–150 \( \mu g/m^3 \) in 0.1 \( \mu g/m^3 \) steps.\textsuperscript{13} The lower and upper bounds of counterfactual concentration with theoretical minimum risk, which indicates no health benefits for reducing PM$_{2.5}$ concentration below certain concentration, were defined as 5.8 and 8.8 \( \mu g/m^3 \), respectively.

In previous global PM$_{2.5}$ health impact assessment studies, the basic unit for the calculation of the health burden attributable to PM$_{2.5}$ was 10 km × 10 km grid cell. They used the global spatially resolved estimates of annual average ambient PM$_{2.5}$ concentrations in 10 km × 10 km resolutions, the global gridded population data within the same resolution, the regional level mortality, and demographic data to calculate the mortality impacts of PM$_{2.5}$. Detailed calculation equations were as follows:

\[
M_{ij} = P_i \times \bar{I}_{jk} \times \left( RR_{jk} - 1 \right)
\]

\[
\bar{I}_{jk} = \frac{I_{jk}}{RR_{jk}}
\]

\[
RR_{jk} = \frac{\sum_{i=1}^{N} P_i \times RR_{jk}(C_i)}{\sum_{i=1}^{N} P_i}
\]

Where \( M_{ij} \) is premature mortality for grid cell i (for disease j) located in region k (consisting of \( N \) sub-grid cells), \( P_i \) is the population in grid cell i, \( I_{jk} \) is the average mortality rate for disease j in region k, \( RR_{jk}(C_i) \) is the IER RR value for the disease j at PM$_{2.5}$ concentration of C (for grid cell i).\textsuperscript{14} To estimate the health benefits (\( \Delta M_{ij} \), change in mortality) of achieving the WHO PM$_{2.5}$ air quality guideline values of 10 \( \mu g/m^3 \), the following equation was used:

\[
\Delta M_{ij} = P_i \times \bar{I}_{jk} \times \left( RR_{jk}(C_i^*) - RR_{jk}(10) \right)
\]

This approach could be very useful for calculating and comparing country level PM$_{2.5}$ health burden by using the global level estimates (population, PM$_{2.5}$ concentration, mortality) in the same unit resolution (10 km × 10 km grid and regional level). However, up to date demographic and mortality data of each country are often not used for the analysis and sub-national level estimates for most of the countries were not available. In addition, 10 km × 10 km grid cell may not clearly reflect the regional differences in the age structure and the mortality rates in various metropolitan cities and provinces of a single country. Besides, the demographic and mortality data are organized in administrative units in most of the countries and thus have to be converted into 10 km × 10 km grid cell levels.

Therefore, we used the same equations but applied minor changes regarding the basic calculation units. Our basic analysis units were ‘si,’ ‘gun,’ and ‘gu,’ the basic administrative units for the metropolitan cities and provinces of Korea. For example, for the calculation of premature mortality in metropolitan cities, the above equation was modified as follows: where \( M_i \) is premature mortality for ‘gu’ i (for disease j) located in metropolitan city k (consisting of \( N \) number of ‘gu’), \( P_i \) is the population in ‘gu’ i, \( I_i \) is the average mortality
rate in metropolitan city k. We applied the same concept for calculating the premature mortality in major provinces by using the population and PM$_{2.5}$ concentration data in ‘si’ and ‘gun’ levels. The 95% confidence intervals for the attributable mortality and the changes in mortality was estimated by applying 2.5% and 97.5% RR values of IER model for certain PM$_{2.5}$ exposure values.

To account for the lag effect of PM$_{2.5}$ exposure, we used annual levels of PM$_{2.5}$ concentration for 2006 (the earliest year with modelled PM$_{2.5}$ data) to calculate number of deaths attributable to ambient PM$_{2.5}$ for 2015 as suggested in the previous article. In addition, we averaged PM$_{2.5}$ concentration from year 2006 to 2015 and estimated the number of deaths attributable to ambient PM$_{2.5}$ for 2015 as a sensitivity analysis. We additionally evaluated the annual temporal trends of the health burden from 2006 to 2015 in metropolitan cities and provinces of Korea by using yearly PM$_{2.5}$ concentration, mortality, and population structure data. SAS version 9.4 (SAS Institute Inc., Cary, NC, USA) and R statistical software (version 3.1.3; R Foundation for Statistical Computing, Vienna, Austria) were used in our analysis.

**Ethics statements**
The Institutional Review Board of the Seoul National University Hospital, Korea, exempted this study from review because we used publicly available population level data from the Korean Statistical Information Service (IRB No. E-1710-004-889).

**RESULTS**
The annual average PM$_{2.5}$ concentration and the population weighted PM$_{2.5}$ concentration for 2015 in Korea were 24.4 µg/m$^3$ and 25.1 µg/m$^3$, respectively. Fig. 1 shows the spatial variation in annual PM$_{2.5}$ concentrations across major metropolitan cities and provinces of Korea. The sub-national regions with the highest PM$_{2.5}$ concentrations (over 30 µg/m$^3$) are located in Incheon metropolitan city (Dong-, Nam-, Namdong-, and Bupyeong-gu) and Gyeonggi (Bucheon-si), Chungcheongnam (Nonsan-si), and Jeollabuk (Jeonju-, Iksan-, Gimje- and Wanju-si) provinces (Supplementary Table 1).

![Fig. 1. Mean concentration of PM$_{2.5}$ and population density by basic administrative unit of the Korea in year 2015. (A) PM$_{2.5}$ concentration and (B) population density. PM$_{2.5}$ = particulate matter less than 2.5 µm in diameter.](https://jkms.org/https://doi.org/10.3346/jkms.2018.33.e193)
The total 11,924 deaths were attributable to PM$_{2.5}$ exposure in 2015 in Korea. Specifically, 3,303 deaths due to IHD, 637 deaths due to COPD, 2,338 deaths due to LC, and 5,646 deaths due to stroke were attributable to PM$_{2.5}$ exposure in 2015 (Table 1). Fig. 2 and Table 1 shows the spatial variation of PM$_{2.5}$ health burden across the sub-national regions. Particularly, deaths attributable to PM$_{2.5}$ exposure were concentrated around Seoul (1,763 deaths), Busan (947 deaths), and Gyeonggi province (2,352 deaths). The number of attributable deaths due to PM$_{2.5}$ according to basic administration level of metropolitan cities and province are summarized at Supplementary Table 1.

General association between annual mean PM$_{2.5}$ concentration and age-standardized mortality rate due to PM$_{2.5}$ exposure in Korea for year 2015 are described in Fig. 3. There was positive correlation between age-standardized mortality rate and annual mean PM$_{2.5}$ concentration. After age-standardization (per 100,000 population), mortality rate attributable to PM$_{2.5}$ exposure was high in Sejong, Daegu, and Incheon metropolitan cities and Jeollabuk and Chungcheongbuk provinces.

By simulating the reduction in the annual mean values of PM$_{2.5}$ according to the WHO guideline value (10 µg/m$^3$), about 8,539 deaths could be averted in Korea (Table 2). By conducting a 9-year time lag analysis with the annual PM$_{2.5}$ concentration of 2006, the total of 13,856 deaths were attributable to PM$_{2.5}$ exposure in 2015 (Supplementary Table 2). In the sensitivity analysis, with an average annual PM$_{2.5}$ concentration from 2006 to 2015, the total 12,808 deaths were attributable to PM$_{2.5}$ exposure in 2015 (Supplementary Table 3).

Most of the metropolitan cities and provinces in Korea showed decreasing or stable temporal trends of the mortality burden attributable to PM$_{2.5}$ from 2006 to 2015 (Fig. 4, Supplementary Tables 4 and 5). Compared to 2006, Seoul, Busan, and Incheon metropolitan cities and Gyeonggi province showed marked decrease in number of attributable deaths due to PM$_{2.5}$ in 2015. However, compared to 2014, Jeollanam and Jeollabuk provinces and Gwangju metropolitan city showed increase in number of attributable deaths due to PM$_{2.5}$ in 2015.

WHO = World Health Organization, PM$_{2.5}$ = particulate matter less than 2.5 µm in diameter.

*Annual mean PM$_{2.5}$ concentration at year 2015.
DISCUSSION

By using PM$_{2.5}$ modeling data, IER functions, and up to date publicly available population and mortality data, we evaluated the health burden attributable to PM$_{2.5}$ in the metropolitan cities and provinces of Korea. The total 11,924 deaths were attributable to PM$_{2.5}$ in Korea in 2015. There was also decreasing trends of the health burden in most of the cities and provinces when compared to 2006. As expected, deaths burden attributable to PM$_{2.5}$ was elevated in the basic administrative units where PM$_{2.5}$ concentration and population density are high.

After age-standardization (per 100,000 population), mortality rate attributable to PM$_{2.5}$ was high in Sejong, Daegu, and Incheon metropolitan cities and Jeollabuk and Chungcheongbuk provinces. Although number of deaths attributable to PM$_{2.5}$ was highest in Seoul metropolitan city and Gyeonggi province, age-standardized rate become relatively low in these two sub-regions. We believe this results comes from high population density of Seoul and Gyeonggi, but relatively low age and disease specific mortality rates compared to other sub-regions of Korea.

Fig. 4. Temporal trends of the health burden attributable to ambient PM$_{2.5}$ exposure in the Korea. (A) Metropolitan cities and (B) provinces.
PM$_{2.5}$ = particulate matter less than 2.5 µm in diameter.
According to 2016 WHO report, a total of 11,523 deaths and 253,512 DALYs were attributable to PM$_{2.5}$ exposure in Korea for 2012. These results are comparable to our estimation of 11,872 deaths for 2012. In the recent GBD 2015 study, premature deaths attributable to PM$_{2.5}$ exposure in Korea in 2005, 2010, and 2015, were 13,094, 13,777, and 18,148 deaths, showing increasing trends in the three most recent five-yearly estimates. However, in our study, the number of deaths attributable to PM$_{2.5}$ generally decreased since 2006 in Korea, even though there were increasing patterns in 2013 and 2014. This discrepancy might have resulted from the use of different PM$_{2.5}$ exposure data, mortality data, and IER functions between this study and that used in the 2015 GBD study. For example, although we used publicly available IER functions of GBD 2010 and 2013 in our study, there was a recent update of the functions with changes in the theoretical minimum risk exposure levels (2.4–5.9 μg/m$^3$) and the model fitting algorithm, which resulted in a higher estimation of RR values compared to the previous GBD studies. Therefore, there are possibilities of underestimation in our study compared to recent 2015 GBD study. However, our study aim was to assess the regional and temporal variations in mortality burden due to PM$_{2.5}$ exposure in Korea and the above changes of RR values may not affect our trend analysis results seriously.

Therefore, we believe that the major discrepancy between our trend analysis and those of the GBD 2015 results may come from the use of different PM$_{2.5}$ exposure data. In the GBD 2015 study, annual mean population weighted exposure levels of PM$_{2.5}$ increased from 25.18 μg/m$^3$ (2010) to 28.66 μg/m$^3$ (2015) in Korea. In our modeling data, the annual mean concentration and the population weighted PM$_{2.5}$ levels were 26.85 μg/m$^3$ and 28.74 μg/m$^3$ for 2010, and 24.47 μg/m$^3$ and 25.13 μg/m$^3$ for 2015, respectively. Because the annual PM$_{2.5}$ exposure data of 2015 used in our study shows about 3 μg/m$^3$ lower levels compared to PM$_{2.5}$ exposure data used in GBD studies, this may results in lower values of number of attributable deaths for year 2015. However, recent country wide monitoring data shows similar results to our PM$_{2.5}$ exposure modelling data. The annual report of air quality in Korea indicated decreasing trends of annual PM$_{10}$ concentration from 2006 to 2015. In addition, the only available nation-wide PM$_{2.5}$ ground monitoring data of 2015 (Seoul: 23, Busan: 26, Daegu: 26, Incheon: 29, Gwangju: 26, Daejeon: 28, Ulsan: 25, all measured in μg/m$^3$) showed comparable results to that of the PM$_{2.5}$ modeling data used in our study (Seoul: 24.2, Busan: 25.9, Daegu: 24.9, Incheon: 27.6, Gwangju: 24.1, Daejeon: 27.2, Ulsan: 24.6 all measured in μg/m$^3$). Therefore, we believe our modeling data is reasonable for the health impact assessment study of PM$_{2.5}$ in the sub-national levels and our study results may contribute additional spatial and temporal information to the global level estimations. However, long term (from 2004 to 2013) particulate matter measurement data from one monitoring site in Seoul showed complicated annual PM$_{2.5}$ concentration patterns, despite their overall decreasing pattern. Therefore, we believe our PM$_{2.5}$ modeling data should be further validated using satellite data and in the future, by a nation-wide ground monitoring data of PM$_{2.5}$.

There are few studies which evaluated the health impacts of particulate matter in Korea. By using modelled PM$_{2.5}$ data, a total number of 15,346 (4,498–26,242) deaths were estimated to be attributable to PM$_{2.5}$ exposure in Seoul, Incheon and Gyeonggi provinces in 2010. Another city level health impact assessment study estimated that about 12,000 deaths can be averted by reducing PM$_{2.5}$ concentrations in the seven metropolitan cities of Korea according to the WHO guideline values of 10 μg/m$^3$. However, these previous results could be overestimated due to the use of the linear exposure mortality functions and by incorporating diverse disease outcomes rather than the four specific disease outcomes (IHD, LC, COPD, and stroke) analyzed in our study and in GBD studies. Another study estimated number of
attributable deaths due to PM$_{2.5}$ exposure by using exposure data of GBD 2013 and linear exposure mortality functions. They estimated that about 16,871 deaths were attributable to PM$_{2.5}$ exposure in year 2013 by LC, IHD, and stroke.

In our study, deaths burden attributable to ambient PM$_{2.5}$ exposure has generally decreased from 2006 to 2015. However, about 52% and 98% of the Korean population are still living in conditions with an annual concentration level of PM$_{2.5}$ greater than the WHO interim Target 2 (25 $\mu$g/m$^3$) and Target 3 (15 $\mu$g/m$^3$) recommendations with our data. There were 43% and 79% of days in Korea, which exceeded WHO interim Target 2 and 3 recommendations in year 2015. Furthermore, nearly all of the total Korean population were living in conditions where annual concentration level of PM$_{2.5}$ are above 10 $\mu$g/m$^3$ and 92% of days were above 10 $\mu$g/m$^3$ in 2015. By decreasing the annual PM$_{2.5}$ concentrations to 10 $\mu$g/m$^3$, about 8,500 deaths in 2015 can be averted. Therefore, despite the decreasing patterns of the PM$_{2.5}$ attributable deaths in our analysis, there is great need for improvement regarding PM$_{2.5}$ in Korea.

Significant decrease in the mortality burden in Seoul, Incheon, and Gyeonggi provinces, which are Seoul Metropolitan Areas (SMA), are worthy of note. In December 2003, the Special Act on the improvement of air quality in SMA was legislated. Based on the Special Act, the first phase of the air quality improvement plan for the SMA (2005–2014) aimed to reduce the annual PM$_{10}$ and nitric oxide concentrations to 40 $\mu$g/m$^3$ and 22 ppb respectively by regulating the total amount of the emissions in the workplace, supplying low-emission vehicles, and strengthening the gas emission management regulations. As a result, ground monitored annual PM$_{10}$ concentration in SMA showed decreasing patterns from 2005 to 2015. Decreasing patterns of the annual PM$_{2.5}$ modeling data and attributable deaths in our study in SMA also indicate the effects of the Special Act in some aspects.

In December 2013, the Ministry of Environment, the Republic of Korea announced the implementation of policy guidelines named the Comprehensive countermeasures against particulate matter. The main measures were, implementation of nationwide forecasting and warning system on particulate matter, enhancing international level cooperation with neighboring countries, and commencing the second phase (2015–2024) of the air quality improvement plan for the SMA. In June 2016, the government unveiled the emission reduction plan and Special Measures on Air Quality, to tackle particulate matter issues, with the intention to reduce the average annual concentration of PM$_{2.5}$ to be comparable to that of European city in 2021 (20 $\mu$g/m$^3$) and 2026 (18 $\mu$g/m$^3$). However, current governmental measures have not considered regional disparities and temporal trends of the health burden attributable to PM$_{2.5}$ exposure. Therefore, we believe our study findings can enable politicians and local government officers to recognize the current sub-national states of the health burden and to estimate potential health benefits by reducing particulate matter concentration in sub-national levels.

Several conventional limitations of PM$_{2.5}$ health-impact assessment studies are known, and particularly, issues regarding the use of IER functions was related to our study. First, IER functions only provide cause specific RR values for IHD, LC, COPD, and stroke for adults. Due to the increasing number of studies reporting the possible association between air pollution exposure and diverse disease outcomes, our study may underestimate the true health burden attributable to PM$_{2.5}$ exposure. Second, because IER functions do not provide the source-specific RR, health impact assessment studies using IER functions rely on the concentration of the particulate matter. Therefore, the different components and sources of the PM$_{2.5}$ at the sub-national regions were not considered in our analysis. However, evidence of different
toxicities from the sources and the components of particulate matters are still lacking.\textsuperscript{24,25} Third, the RR estimates of large-scale cohort studies used to model IER functions were based on studies conducted in western countries where the annual PM\textsubscript{2.5} values are relatively low, compared to Korea. Although IER functions are believed to provide reasonable estimates of RR values at higher PM\textsubscript{2.5} concentrations,\textsuperscript{3} large scale cohort studies evaluating PM\textsubscript{2.5} exposure and mortality outcomes in regions with high levels of PM\textsubscript{2.5} concentrations are needed to generate more precise estimates for the calculation of the health burden in polluted countries. Therefore, cohort studies evaluating the association between chronic PM\textsubscript{2.5} exposure and mortality outcomes in Korea are needed in the future. Finally, for trend analysis of HIA, we used yearly PM\textsubscript{2.5} concentration, demographic, and mortality data. Therefore, results of the trend analysis should be interpreted with caution due to the lag effects of particulate exposure on several chronic disease outcomes evaluated in this study. In addition, number of attributable deaths due to PM\textsubscript{2.5} exposure depends on not only annual PM\textsubscript{2.5} concentration, but also population structure and age and disease specific mortality data. Therefore, improvements on medical quality and system of Korea during 2006–2015 can also affect the trend analysis results.

In conclusion, about 11,924 premature deaths were attributable to PM\textsubscript{2.5} exposure in 2015 in the Republic of Korea. Our findings show that further actions to improve air quality in Korea would substantially improve health burden. Due to the spatial variations attributable to PM\textsubscript{2.5}, future particulate matter resolution policies should be reflective of the city and province level health-impact assessment results.
